GRAPHICAL ABSTRACT

An efficient and catalyst free one pot synthesis of N-benzylloxazolidinone derivatives is developed by reaction of N-benzyl-β-amino alcohol derivatives and N, N-carbonyldiimidazole (CDI) in DMSO. A range of novel N-benzylloxazolidinone derivatives were synthesised by using this one pot methodology with good to excellent yields.

Keywords: Oxazolidinones, N-benzyl-β-amino alcohol, N,N-carbonyldiimidazole, Heterocycles.

INTRODUCTION

The effectiveness of latest generation of antibiotics is gradually decreasing towards the treatment of numerous infectious diseases due to the newly emerging resistance mechanism developed inside the microbial. This led to the extensive research and there by discovery of new antibiotics for the treatment of various diseases. N-Aryloxazolidinones and the corresponding derivatives are known to be effective against vancomycin-resistant enterococci (VRE) and methicillin-resistant Staphylococcus aureus (MRSA) [1-3]. The oxazolidinone derivatives, Linezolid and Posizolid (Figure 1) are found to be active against bacterial infection. Interestingly oxazolidinones also have shown pharmacological activity as antidepressant and antisychoisis [4-6]. Toloxatone and Befloxatone (Figure 2) are used for the treatment of depression as a reverse inhibitor of MAO-O [7-12]. Some of the oxazolidinone derivatives are also employed as key structural fragments in biologically active materials for pharmaceutical use [13-14] and also as auxiliaries in useful synthetic conversations [15-16].

INTRODUCTION

The effectiveness of latest generation of antibiotics is gradually decreasing towards the treatment of numerous infectious diseases due to the newly emerging resistance mechanism developed inside the microbial. This led to the extensive research and there by discovery of new antibiotics for the treatment of various diseases. N-Aryloxazolidinones and the corresponding derivatives are known to be effective against vancomycin-resistant enterococci (VRE) and methicillin-resistant Staphylococcus aureus (MRSA) [1-3]. The oxazolidinone derivatives, Linezolid and Posizolid (Figure 1) are found to be active against bacterial infection. Interestingly oxazolidinones also have shown pharmacological activity as antidepressant and antisychoisis [4-6]. Toloxatone and Befloxatone (Figure 2) are used for the treatment of depression as a reverse inhibitor of MAO-O [7-12]. Some of the oxazolidinone derivatives are also employed as key structural fragments in biologically active materials for pharmaceutical use [13-14] and also as auxiliaries in useful synthetic conversations [15-16].
Recently, Anacetrapib which contains an oxazolidine core has been identified as ETP inhibitor (Figure 3) and is currently being studied in clinical trials [17]. Locostatin, an oxazolidinone derivative is found to be useful in controlling inflammation, sepsis, and autoimmune diseases [18].

The most common synthetic routes reported so far for the synthesis of N-benzylloxazolidinones includes N-benzyl-β-amino alcohols [20-24]. The methods reported so far either involves use of metal catalyst or use of carbon dioxide in the presence of catalyst.

N,N-Carbonyldiimidazole (CDI) is a widely used reagent in organic synthesis. It is frequently used as a replacement for the highly toxic Phosgene in reactions with alcohols and amines [25-26] and the by- product imidazole formed after the reaction can be easily removed by dilute acid wash. Based on this, we tried to use CDI as a reagent in our synthesis of N-benzylloxazolidinones and successfully developed a catalyst free approach for the synthesis of N-benzylloxazolidinones (2) from N-benzyl-β-amino alcohol derivatives (1) using N,N-carbonyldiimidazole (CDI) in DMSO (Scheme 1).

**Scheme 1: One pot synthesis of N-benzylloxazolidinones.**

**MATERIALS AND METHODS**

All reagents were used as received from commercial sources without further purification or prepared as described in the literature. Reactions were stirred using Teflon-coated magnetic stirring bars. TLC plates were visualized by ultraviolet light or by treatment with a spray of Pancaldi reagent \((\text{NH}_4)_6\text{MoO}_4\cdot\text{Ce(SO}_4\text{)}_2\cdot\text{H}_2\text{SO}_4\cdot\text{H}_2\text{O}\). Chromatographic purification of products was carried out by flash column chromatography on silica gel (60-120 mesh). Melting points were determined using an electro thermal melting point apparatus and are uncorrected. Infrared spectra were recorded on a Perkin-Elmer 1650 Fourier transform spectrometer. NMR spectra were measured in CDCl₃, acetone, DMSO-d₆ (all with TMS as internal standard) on a Varian Gemini 400 MHz FT NMR spectrometer magnetic resonance spectrometer. Chemical shifts (δ) are reported in ppm, and coupling constants (J) are in Hz. The following abbreviations were used to explain the multiplicities: s = singlet, d = doublet, t= triplet, q = quartet, m = multiplet. Mass spectra were recorded on an HP-5989A quadrupole mass spectrometer.

**EXPERIMENTAL**

**General method for the preparation of β-Aminoalcohol (2a-h)**

Ethanolamine (1.0 mmol) was added to a stirring solution of Aromatic aldehyde (1 mmol) dissolved in methanol (5 mL) and stirred at 25-30°C for 1 h. After 1 h, sodium borohydride (0.5 mmol) was added, and stirred at 25-30°C for 2 h under nitrogen atmosphere. After the completion of reaction, quenched the reaction mass with water, extracted the product with ethyl acetate and washed with water. Dried the organic layer with sodium sulphate and distilled under vacuum to get the required β-Aminoalcohol.

**General method for the preparation of Substituted oxazolidinones derivatives (2i-l)**

β-Aminoalcohol (1.0 mmol) was dissolved in DMSO (2 mL) and added carbonyldiimidazole (1.5 mmol) under nitrogen atmosphere and stirred at 23-30°C for 2-3 h. After the completion of reaction, reaction mass was diluted with water and extracted the product with ethyl acetate. Washed the ethyl acetate layer with dilute HCl solution followed by with water. Dried the organic layer with sodium sulphate and distilled under vacuum to get the pure product.

**3-benzylloxazolidin-2-one (2a)**

1H-NMR (400 MHz, CDCl₃): δ (ppm)=7.37-7.26 (m, 5H), 4.42 (s, 2H), 4.31-4.27 (m, 2H), 3.43-3.39 (m, 2H); 13C-NMR (100 MHz, CDCl₃): δ (ppm)=158.53, 135.76, 128.83 (2C), 128.16 (2C), 127.98, 61.76, 48.42, 43.95; HRMS: m/z [M + H] calculated for C₁₆H₁₂NO₂: 178.0868; found: 178.0865.
RESULTS AND DISCUSSION

The \( \text{N-benzyl-\( \beta \)-amino alcohol derivatives} \) required for the synthesis were prepared from benzaldehyde derivatives and ethanolamine following the same procedure reported by Xiong-Jie and his team \cite{11}. Initially, the reaction was performed by stirring beta amino alcohol 1a and CDI in DCM at room temperature for 15 h. To our delight \( \text{N-benzyl-\( \beta \)-amino alcohol} \) 2a was obtained in 30% yield along with the recovery of the unreacted intermediate \( \text{N-benzyl-\( \beta \)-amino alcohol} \) (Entry1, Table 1). Attempts were made to increase the product yield by extending the reaction time or temperature (Entry 2 & 3, Table 1). But these attempts did not show any significant increase in the product yield. Other solvents like THF, DMSO and DMF (Entry 4, 5 & 6, Table 1) were also screened for the reaction. Among the solvents, DMSO was found to be optimum for the reaction and the yield remarkably improved to 94%. Only 25% of the product formation was observed in THF however considerable amount of product (70%) was obtained by using the DMF solvent. Further attempts were made to improve the yield in DMSO by increasing the reaction temperature (Entry 7, Table 1) however did not get any positive result. Overall, the reaction conditions presented for the entry 5 in Table 1 found to be superior to other screening experiments.

*aReactions were carried out using 1a (1.0 mmol) and CDI (1.5 mmol) in a solvent at room temperature under nitrogen; †Isolated yield.*

The scope and generality of the reaction was further tested by performing the reactions using variety of N-benzyl-β-amino alcohol derivatives (1). Substituents such as Cl, Br, F, NO₂ on the benzene ring (entries 1-6, Table 2) were well tolerated. The reaction proceeded well in all these cases affording desired N-benzyloxazolidinones 2 in good to excellent yields.

All the N-benzyloxazolidinone derivatives (2a-h) synthesized were characterised by their ¹H and ¹³C-NMR and HRMS data and further confirmed by comparing with the data reported for these compounds in literature.

We have also extended this methodology for the preparation of functionalised oxazolidinone derivatives (4a-d, Table 3). The methodology worked well for the synthesis of these derivatives.

CONCLUSION

In conclusion, we have reported a simple and efficient one pot synthesis of N-benzyl-oxazolidinones from N-benzyl-β- amino alcohols and CDI in DMSO in good to excellent yields. The methodology does not require any use of base, catalyst or hazardous solvents.

ACKNOWLEDGEMENT

The authors would like thank the management of Dr. Reddy’s Laboratories Limited for providing support to carry out this work. We also thank the analytical department of Dr. Reddy’s Laboratories for providing timely support.
