ABSTRACT

The inhibition effect of Benzimidazole on Mild Steel in (HNO$_3$ + HCl) binary acid mixture was studied by weight loss, Temperature effect methods and polarization techniques. Rate of Corrosion was increases with increase in concentration of acid mixture. The inhibition efficiency of Benzimidazole increased as the concentration of Benzimidazole Increased. The inhibitor is found to be an excellent corrosion inhibitor from the results obtained. The inhibition action depends on the chemical structure, concentration of the inhibitor and concentration of the corrosive medium. The values of activation energy ($E_a$), free energy of activation ($\Delta G^\circ_{ads}$), Heat of adsorption ($Q_{ads}$), enthalpy of adsorption ($\Delta H^\circ_{ads}$) and entropy of adsorption ($\Delta S^\circ_{ads}$) were calculated. Corrosion rate increases while I. E. decreases with rise in temperature.

Key words: Corrosion, Mild Steel, Nitric and Hydrochloric acid mixture, Benzimidazole.

INTRODUCTION

Mild steel is extensively used in industries because of its low cost and availability, as a result corrodes when exposed to various industrial environments and conditions. Acid solutions are generally used for the removal of undesirable scale and rust in several industrial processes. Inhibitors are generally used to control metal dissolution. The inhibition of corrosion in acid solutions can be secured by the addition of a variety of organic compounds and has been investigated by several researchers [1-4]. Most of the well known acid inhibitors are organic compounds containing O, S and/or N atoms [5-6]. Ethylamines, Xylenol orange, Pyridazine, Polyvinyl pyrrolidone, Ethanolamines, Neem (Azadirachta indica) mature leaves extract, biodegradable (VPAP and VOAP) etc. have been extensively investigated as corrosion inhibitors [7-13].

N-heterocyclic compounds act by adsorption on the metal surface, and the adsorption takes place through nitrogen atom, as well as with triple or conjugated double bonds or aromatic rings in their molecular structures. Many N-heterocyclic compounds, such as imidazoline, triazole, pyrimidine, pyrole, pyridine, etc., derivatives [14-17], have been used for the corrosion inhibition of iron or steel in acidic media.

In this paper, the role of Benzimidazole in inhibiting the corrosion of Mild steel in (HNO$_3$ + HCl) binary acid mixture has been reported.

MATERIALS AND METHODS

The mild steel used had the following chemical composition (0.025% C, 0.013% Si, 0.010% S, 0.014% P, 0.210% Mn, 0.008% Ni, 0.007% Cr, 0.002% Mo, 0.006% Cu, 0.059% Al and balance Fe).
Rectangular specimens of Mild Steel of size (5.10 cm x 2.04 cm x 0.12 cm thickness) with a small hole of ~2 mm diameter just near one end of the specimen were used for the determination of corrosion rate. All the specimens were cleaned by buffing and wrapped in plastic bag to avoid atmospheric corrosion. A specimen, suspended by a glass hook, was immersed in 200 ml of three different concentration test solution at 300 ± 1 K for 24 h. After the test, the specimens were cleaned by using wash solution prepared by adding 2% Sb₂O₃ (antimony Oxide), 5% SnCl₂ (stannous chloride) in concentrated HCl (100 ml) at room temperature with constant stirring about 15-20 mins [18-19], washed with water, cleaned with acetone and dried in air.

To study the effect of temperature on corrosion of Mild Steel in binary acid mixture (0.01 M HNO₃ +0.01 M HCl), the specimens were immersed in 200 ml of corrosive solution and corrosion rate was determined at various temperatures e.g. at 300, 310, 320 and 330 K for an immersion period of 3hr with and without inhibitor. From the data, I.E.(in %), energy of activation (Ea), heat of adsorption (Qads), free energy of adsorption (ΔG⁰ads), change of enthalpy (ΔH⁰ads) and entropy of adsorption (ΔS⁰ads) were calculated.

For polarization study, metal specimen having an area of 0.0025 dm² was used. Corrosion behavior of Mild steel samples were tested in (0.05M HNO₃ + 0.05M HCl) & (0.05M HNO₃ + 0.05M HCl) + Benz imidazole solutions using potentiostat Gamry Reference 600. Corrosion cell which consists of Calomel electrode as reference electrode, graphite rod as counter electrode and test samples as working electrode.

RESULTS AND DISCUSSION

The results are given in Tables 1 to 4. To assess the effect of corrosion of Mild steel in (HNO₃+ HCl) binary acid mixture, Benz imidazole was added as an inhibitor. I.E. was calculated by the following formula.

\[ I.E. (\%) = \left( \frac{(W_u - W_i)}{W_u} \right) \times 100 \] (1)

Where, \( W_u \) is the weight loss of metal in uninhibited acid and \( W_i \) is the weight loss of metal in inhibited acid.

Energy of activation (Ea) has been calculated with the help of the Arrhenius equation [20].

\[ \log \left( \frac{\rho_2}{\rho_1} \right) = \frac{E_a}{2.303 R} \left[ \left( \frac{1}{T_1} \right) - \left( \frac{1}{T_2} \right) \right] \] (2)

Where \( \rho_1 \) and \( \rho_2 \) are the corrosion rate at temperature \( T_1 \) and \( T_2 \) respectively.

The values of heat of adsorption (Qads) were calculated by the following equation [20].

\[ Q_{ads} = 2.303 R \left[ \log \left( \frac{\theta_2}{1 - \theta_2} \right) - \log \left( \frac{\theta_1}{1 - \theta_1} \right) \right] \times \frac{T_1 \times T_2}{T_2 - T_1} \] (3)

Where, \( \theta_1 \) and \( \theta_2 \), \( \theta = (W_u - W_i) / W_i \) are the fractions of the metal surface covered by the Inhibitors at temperature \( T_1 \) and \( T_2 \) respectively.

The values of the free energy of adsorption (ΔG⁰ads) were calculated with the help of the following equation [21].

\[ \log C = \log \left( \frac{\theta}{1 - \theta} \right) - \log B \] (4)

Where, \( \log B = -1.74 - (\Delta G^0 / 2.303 RT) \) and C is the inhibitor concentration.

The enthalpy of adsorption (ΔH⁰ads) and entropy of adsorption (ΔS⁰ads) are calculated using the following equation [22].

\[ \Delta H^{0}_{ads} = E_a - RT \] (5)
\[ \Delta S^{0}_{ads} = \frac{\Delta H^{0}_{ads} - \Delta G^{0}_{ads}}{T} \] (6)

Table-1 shows that corrosion rate increases with increase in concentration of mix acid while % of I.E. decreases. Also as concentration of inhibitor increases corrosion rate decreases while % of I.E. increases.

Table-2 shows that as the temperature increases, Corrosion rate increases while % of I.E. decreases. Mean Ea values were calculate by using equation (2) for mild steel in 0.01 M Binary acid mixture is 20.934 KJmol⁻¹ while acid...
containing inhibitors the mean Ea values were found to be higher than that of uninhibited system (table-2). The higher values of mean Ea indicate physical adsorption of the inhibitors on metal surface.

From Table-3 it is evident that the values of Qads were found to be negative and lies in the range of -42.598 to -20.830 KJmol⁻¹. Oguzje [23] explained that the degree of surface coverage decreased with rise in temperature. The higher negative values of heat of adsorption also show that the inhibition efficiency decreased with a rise in temperature.

From Table-3 the negative $\Delta G^0_{ads}$ values ranging from -19.37 to -16.05 KJmol⁻¹ indicate that the adsorptions of the inhibitors are spontaneous. The most efficient inhibitor shows more negative $\Delta G^0_{ads}$ value. This suggests that they are strongly adsorbed on the metal surface. The higher negative values of heat of adsorption also show that the inhibition efficiency decreased with a rise in temperature.

Anodic and cathodic polarization curve without inhibitor shown in figure -1 and with inhibitor shown in figure-2 indicates polarization of both anodes and cathodes. I.E. calculated from corrosion current obtained by extrapolation of the cathodic and anodic Tafel constants are given in Table-4.

**Mechanism:** The mechanism of inhibition of corrosion is generally believed to be due to the formation and maintenance of a protective film on the metal surface. Mild Steel dissolves in (HNO₃ + HCl) acid mixture.
